Measuring Rivers

Collecting accurate information about a river's features and metrics is one of the most important aspects of successful river management.

Metrics can be measured in the field or remotely, or estimated using relational equations.

Field methods include **visual inspection** or **physical measurement** of features. Noting rock-staining from floods to define channel edges is a visual inspection. Using a ruler to determine rock size is a physical measurement. Some remote sensing tools can be applied in the field, such as laser-**range-finders** used to map channel cross-sections.

Category	Method	Description	Watershed	Channel Banks	Channel Pattern	Bed Material	Dimensions	Hydraulics	Slope	Vegetation	Accuracy
Field Based	Visual	Human-based assessment		Y						Y	Low
	Physical	In-situ measurement requiring contact with feature.		Y		Y	Y	Y	Y	Y	High
	Ranging	Field-based remote-sensing using radar, laser, or acoustic ranging.		Y		Y	Y		Y	Y	High
Remote Sensing	Aerial Photos	Passive collection of electromagnetic data from an air- or satellite-borne unit.	Y	Y	Y		Y			Y	Med- High
	Elevation Models	Digital terrain models. Various sources.	Y		Y				Y		Low
	LiDAR	Elevation model from airborne laser emission and detection unit. Can detect and filter out vegetation and buildings.	Y	Y	Y		Y		Y	Y	Med- High
Relational Equations	Regional Regression	Empirically-derived equations relating hard-to-measure physical features to more readily available ones.	Y					Y	Y		Low

Remote-sensing usually refers to information collected by aircraft or satellites. Digital elevation models (DEM) can be generated using radar or LiDAR, or through analysis of photographs. LiDAR is similar to radar, and produces high-resolution **DEMs** that can processed to remove vegetation and structures. Aerial photography is also important remotesensing tool.

Relational equations

approximate the values of certain hard-to-determine river metrics based on features that are more easily measured. This concept is commonly applied through "regional regression equations," which estimate a channel's dimensions and hydraulics based on watershed size. Equations are developed for specific regions.
